**Abstract.** Keyphrase extraction aims to identify a small set of phrases that best describe the content of text. The automatic generation of keyphrases has become essential for many natural language applications such as text categorization, indexing, and summarization. In this paper, we propose **MULTPAX**, a multitask framework for extracting *present* and *absent* keyphrases using pre-trained language models and knowledge graphs. In particular, our framework contains three components: first, **MULTPAX** identifies present keyphrases from an input document. Then, **MULTPAX** links with external knowledge graphs to get more relevant phrases. Finally, **MULTPAX** ranks the extracted phrases based on their semantic relatedness to the input document and return top-k phrases as a final output. We conducted several experiments on four benchmark datasets to evaluate the performance of **MULTPAX** against different state-of-the-art baselines. The evaluation results demonstrate that our approach significantly outperforms the state-of-the-art baselines, with a significance t-test $p < 0.041$. Our source code and datasets are public available at https://github.com/dice-group/MultPAX.

**Keywords:** Present keyphrase extraction · Absent keyphrase generation · Knowledge graph · Pre-trained language models

1 Introduction

Keyphrase extraction is the process of extracting a small set of phrases that best describe a document. This process has been leveraged for several downstream applications, including text summarizing, organizing, and indexing [16]. In the literature, keyphrase extraction is divided into two sub-tasks: (i) detecting present keyphrases (PKE) that appear in a document, and (ii) generating absent keyphrases (AKG) that do not appear in the original document, but are essential for downstream applications (e.g., text summarization, indexing). Table 1 shows an example of extracting present and absent keyphrases from an input text.

Existing works mostly focus on extracting present keyphrases from an input text, including supervised learning (e.g., sequence labelling [22]), and unsupervised learning (e.g., TextRank [17], YAKE [4]). By contrast, generating absent
**Table 1.** Example of present and absent keyphrase extraction from Inspec dataset. The predicted present keyphrases are in italic, and the absent ones are highlighted in gray.

Keyphrase Extraction Using Language Models and Knowledge Graphs

305

DBpedia, BabelNet). For this purpose, we developed a new version of the MAG framework [18], which is optimized for linking keywords and extracting related terms. iii) Finally, we rank all keyphrases (i.e., present and absent) based on their semantic similarity to the input document. The top-\(k\) phrases are returned as the final keyphrases output.

Additionally, we propose an improved metric for evaluating predicted keyphrases based on their semantic-matching with ground-truth keyphrases. Existing studies [13,15,32] consider precision, recall, and \(F_1\) based on the exact-matching between predicted and ground-truth keyphrases, which yields reasonable evaluation for present keyphrases that appear in text. However, in evaluating absent keyphrases, the exact-matching demonstrated an inefficient assessment of words that are semantically similar but are literally different [21]. As an example, assume “Cryptocurrency” as a ground-truth keyphrase, and a keyphrase model was able to generate “Bitcoin” as a predicted keyphrase. In this case, the exact-matching metric ignores the semantic relatedness between both words and considers them completely unrelated. By means of words embeddings, these words are similar and adjacent to each other in the embedding space. In this regard, we propose using an embedding-based \(F_1\)-score to evaluate keyphrases extraction in a more accurate semantic way.

To evaluate the performance of MULTPAX, we conducted several experiments on four benchmark datasets, where we study the performance of our system against different approaches. The evaluation results show that our approach significantly outperforms the state-of-the-art baselines with a significance t-test \(p < 0.041\) and \(F_1\)-score up to 0.535. The main contributions in this paper can be summarized as follows:

- We propose an unsupervised multitask framework that not only extracts present keyphrases, but also generate absent ones.
- To the best of our knowledge, our approach is the first attempt that leverages existing knowledge graphs for keyphrases generation without the need to create keyphrases vocabularies or phrase banks.
- We introduce an embedding-based \(F_1\) evaluation that considers semantic similarity between generated and ground-truth keyphrases rather than the existing exact-matching.
- We carried out several experiments on four benchmark datasets. The evaluation results showed that our approach proved to be more accurate compared with state-of-the-art baselines.

2 Related Work

In this section, we give an overview of the related approaches in unsupervised keyphrase extraction and absent keyphrase generation.

2.1 Unsupervised Keyphrase Extraction

Several approaches have recently been developed for extracting keyphrases in unsupervised setting without the need for annotated data. For example, statistic-
tical approaches such as TF-IDF and YAKE \cite{4} compute statistical features (e.g., word frequencies and co-occurrences) to find important words as candidates for present keyphrases. Moreover, graph-based approaches like TextRank \cite{17} construct a graph representation of text, where words are represented as nodes and their co-occurrences as edges. Thereafter, a node ranking algorithm (e.g., PageRank) is used to sort words, and return top-$k$ words as candidate keyphrases. \cite{3} proposed TopicRank, a graph-based approach similar to TextRank. In the first step, candidate phrases are clustered into topics and then ranked based on with their importance in the document.

Recent studies have demonstrated that embedding-based models can achieve significant results in extracting keyphrases. For example, EmbedRank \cite{2} approach uses part-of-speech tags to extracts potential keyphrases from an input document. Then, EmbedRank uses a pre-trained embedding model to represent both phrases and an input document as low-dimensional vectors. Candidate keyphrases are then ranked based on their Cosine similarity scores to the document’s embedding vector. Although pre-trained language models have shown promising performances for extracting present keyphrases, they have failed to generate absent keyphrases from their lexical corpus. Furthermore, \cite{13} pointed out that embedding-based models ignore local information in a document. Accordingly, they developed a jointly-trained model to incorporate global and local context of a document. In the global view, their approach represented candidate keyphrases and the input document as low-dimensional vectors into one semantic space. After that, the similarity between each candidate keyphrase and the document is computed. In terms of the local context, the authors built a graph structure based on the document context, where nodes represent phrases and edges represent similarities between them. Finally, the output keyphrases are ranked based on this global and local information.

2.2 Absent Keyphrase Extraction

Many previous approaches have relied on sequence-to-sequence models—with encoder-decoder architecture—to generate absent keyphrases \cite{6}. By doing so, sequence-to-sequence models are able to decode not only keyphrases that appear in source text, but also those that may be absent, i.e., the ones that are not explicitly mentioned in the text. However, additional mechanisms need to be integrated to improve the generation of absent keyphrases. For example, \cite{31} applied a Graph Neural Network (GNN) to capture knowledge from related references in scholarly publications. A neural topic model is employed in \cite{28} to expand the context of the decoding component to generate more absent keyphrases.

It is noteworthy that \cite{32} achieved significant results in extracting keyphrases by dividing this task into two sub-tasks: present keyphrase extraction and absent keyphrase generation. Furthermore, the authors proposed a multitask approach to select, guide, and generate keyphrases. In the select module, the authors used a BiLSTM to predict whether a sentence has a keyphrase or not. Then, a guider network is employed to utilize the attention information and memorize the predictions of the selector. Finally, this information is fed to a generator network.
to generate absent keyphrases by selecting words from both the source text and a predefined vocabulary. In addition to these fully-supervised approaches, there are also some unsupervised methods that achieved promising results in generating keyphrases without the need for labelled data. [24] observed that many keyphrases absent from an input document appeared in other related documents. Therefore, they constructed a phrase bank of all keyphrases in a corpus. Then, they identified present keyphrases in relevant documents as candidates for absent keyphrases for the input document. In addition, they employed present keyphrases as silver labels to train a sequence-to-sequence model. Finally, all keyphrases (both present and absent) were ranked based on their lexical and semantic similarity to an input document.

3 Our Approach

In this section, we present our approach for extracting present and absent keyphrases. Figure 1 depicts the architecture of our MULTIPAX framework, including three components: i) present keyphrase extraction (PKE), ii) absent keyphrase generation (AKG), and iii) Keyphrases Semantic Matching.

3.1 Problem Formulation

Let $D$ be an input document with $|S|$ sentences; each sentence $s \in S$ is a sequence of $|s|$ tokens $T = \{t_1, t_2, \cdots, t_{|s|}\}$. Our goal is to build a keyphrase model that not only extracts present keyphrases $Y_p = \{y_{p1}, y_{p2}, \cdots, y_{|Y_p|}\}$ but also generates absent keyphrases $Y_a = \{y_{a1}, y_{a2}, \cdots, y_{|Y_a|}\}$ that are relevant to $D$ by leveraging knowledge graphs such as DBpedia [1] and BabelNet [19].

Following previous works [8, 22], we divide the task of keyphrase extraction into two sub-tasks: Present Keyphrase Extraction (PKE) and Absent Keyphrase Generation (AKG). Furthermore, we define the computation of final keyphrases as a Semantic Matching task. First, we consider PKE as a ranking problem, where candidate phrases are extracted and then ranked based on their similarities to the input document (see Sect. 3.2). Second, we formulate AKE as a linking problem to infer relevant information from external knowledge graphs. For this task, we employ an unsupervised entity-linker [23] that maps a present keyphrase ($Y_p$) to its corresponding entity in a knowledge graph (i.e., DBpedia, BabelNet) and then get relevant terms (e.g., from dct:subject, gold:hypernym properties) as candidates for absent keyphrases. Finally, all keyphrases $Y_p \cup Y_a$ are ranked based on their similarities to $D$, the top-$k$ keyphrases are returned as the final output.

3.2 Present Keyphrase Extraction (PKE)

We employ the BERT language model [7] to extract present keyphrases based on their semantic similarity to a document. The main steps are as follows: (1) We tokenize an input document $D$ into n-gram phrases and annotate each token
Fig. 1. The architecture of MULTPAX framework with three components: present keyphrase extraction, absent keyphrase generation and semantic matching

with part-of-speech tags (e.g., ADJ: adjectives, NOUN: nouns, VERB: verbs).
(2) Then, we remove stop words and keep noun phrases that consist of zero or more adjectives followed by one or multiple nouns [27]. (3) We employ the pre-trained language model (BERT-Encoder) to encode candidate keyphrases as low-dimensional vectors together with the input document into one embedding space.

A special preprocessing is applied to the input text of the BERT-Encoder as follows: a [CLS] token is added at the beginning of each sentence, which is then used to obtain the contextualized embeddings vector of a sentence. An additional token [SEP] is inserted to mark the end of a sentence. Afterward, the input is tokenized by WordPiece tokenizer [25]; each token \( t_i \) is associated with three types of embeddings: token embeddings \( E_{t_i} \) which represents the vocabulary index of each token, segmentation embeddings that distinguishes between input sentences \( E_A \) or \( E_B \), and position embeddings \( E_i \) to indicate the position of each word. The output of the BERT-Encoder is the sentence’s representation matrix \( H = [h_0, h_1, \ldots h_{|S|}] \), where \( h_i \) denotes the embedding vector of token \( t_i \).

Formally, the embedding vector of a sentence \( s_j \) is

\[
H_j = \text{BERT-Encoder}([t_1, t_2, \ldots t_{|s|}]). \tag{1}
\]

Pooling is an essential operation for creating sentence and document embeddings [5]. It is commonly used to aggregate (e.g., mean, max) multiple representations (e.g., sentences) into one embedding vector. To obtain the document’s embeddings \( H_D \), we employ a MaxPooling layer on top of all sentences’ representations. Formally,

\[
H_D = \text{MaxPooling}([H_1, H_2, \ldots H_{|S|}]). \tag{2}
\]
Finally, we use Cosine distance to compute similarities between the embedding vectors of candidate keyphrases $\mathcal{H}_i \in H_{\mathcal{S}}$ and the document embedding $\mathcal{H}_D$. We select the top-$k$ keyphrases as candidates for present keyphrases.

3.3 Absent Keyphrase Generation (AKG)

To obtain absent keyphrases, we first link all present keyphrases $\mathcal{Y}^p$ to a knowledge graph and get additional surface forms (i.e., strings that could be synonyms or alternative names). We consider the DBPEDIA knowledge graph since it provides surface forms for a wide range of common entities. For entity linking, we follow a similar approach to the MAG framework [18].

MAG extracts entity links using two steps: candidate generation and candidate disambiguation. In the candidate generation step, MAG aims to find candidate links $(C_1, \ldots, C_n)$ for pre-marked entities in the search index [18]. To this end, MAG uses acronyms and labels in a knowledge graph to map premarked entity spans from the input text to candidate entities. Furthermore, MAG also relies on the Concise Bounded Description (CBD)\(^1\) of the entities in a knowledge graph by comparing the context of the entity spans in the input document and the CBD of an entity in a knowledge graph [18]. We keep this candidate generation step from MAG and apply it to the extracted present keyphrases from the PKE component. In the candidate disambiguation step, MAG generates a local graph using a breadth-first-search method for all candidate entities on a knowledge graph. Then, MAG applies the HITS ranking algorithm [11] to jointly rank the candidate links for all entities in the local graph. HITS ranks the nodes in a directed graph based on incoming and outgoing edges. Authorities are seen as nodes, that carry important information, while hubs are nodes, that point to a large amount of authority nodes. So the authority score of a node $n$ is calculated based on the hub score of the nodes, that have a directed edge to the node $n$, while the hub score of $n$ is calculated based on the authority score of the nodes which are linked by $n$ [11]. Formally, HITS calculates the authority score $a_p$ for the node $p$ as

$$a_p = \sum_{q: (q,p) \in G} h_q,$$

where $h_q$ is the hub-score for the node $q$, given that a directed edge from node $q$ to node $p$ exists in the graph $G$. The hub-score $h_p$ for a node $p$ is calculated as

$$h_p = \sum_{q: (q,p) \in G} a_q,$$

where $a_q$ is the authority-score for a node $q$, which is linked by node $p$ [11]. $a_q$ and $h_p$ are initialized randomly and updated iteratively until convergence.

In contrast to MAG, we not only link present keyphrases, but also extract related terms for each linked keyphrase from a knowledge graph. Furthermore, we extract top-ranked candidates for each entity and $n$ nodes with the highest

\(^1\) https://www.w3.org/Submission/CBD/.
authority scores in the local graph, since their surface forms could be used as candidates for the absent keyphrases. In our approach, we use BABELNET to find hypernyms for the present keyphrases, in addition to the surface forms from DBPEDIA.

3.4 Keyphrases Semantic Matching

In the last component, we aim to identify top-k relevant keyphrases (present and absent), we set \( k = \{5, 10, 20\} \) in our experiments. We regard this task as a semantic textual similarity [14]. To match similarities between a document \( D \) and candidate keyphrases, we embed them into one semantic space using a pre-trained embedding model. Then we employ Cosine distance to find top-k nearest keyphrases \( (H_i) \) to the document’s vector \( H_D \) and return as final keyphrase predictions. Formally,

\[
\text{Cos}(H_i, H_D) = \frac{H_i \cdot H_D}{||H_i|| \times ||H_D||}.
\]

where \( H_i \) donates the embedding vector of candidate keyphrase (present \( y_i^p \) or absent \( y_i^a \)), and \( H_D \) represents the embedding vector of the input document.

4 Experiments

We conducted our experiments to answer the following research questions:

\( Q_1 \). How efficient is our approach in extracting present keyphrases compared to the state-of-the-art approaches?

\( Q_2 \). Are the existing exact-matching metrics (i.e., Precision, Recall and F\(_1\)-score) suitable for evaluating absent keyphrases?

\( Q_3 \). To what extent does each component in our framework contribute to the overall performance?

4.1 Experimental Setup

Datasets. In our experiments, we used four benchmark datasets of English documents, namely, Inspec [9], SemEval2010 [10], Krapivin [12], and NUS [26]. Table 2 provides a statistical overview of each dataset, including the total number of documents (#Doc.), the number of documents in the evaluation set (#Test), average keyphrases per document (Avg. KP) and the ratio of absent keyphrases in each dataset (Ratio%).

Baselines. We compared our approach with the following baselines for extracting keyphrases:

- **TextRank** [17] is an unsupervised approach that constructs a graph representation from a document, where nodes represent phrases and their edges are computed based on lexical similarities. Further, TextRank uses the PageRank algorithm to extract present keyphrases.
- **YAKE** [4] is a simple unsupervised method that extracts keywords automatically based on statistical features such as words co-occurrence and frequencies.
- **EmbedRank** [2] is an unsupervised method that employs words embeddings to identify relevant words to a document as candidate keyphrases. Furthermore, EmbedRank utilizes the Maximum Marginal Relevance algorithm to increase the diversity of the extracted keyphrases.
- **Supervised-CopyRNN** [15] is a supervised baseline that trains a sequence-to-sequence model with a copy mechanism on KP20K dataset [15]. We used this approach as a baseline for present keyphrases extraction as well as absent keyphrase generation to compare the performance of copy mechanism.
- **AutoKeyGen** [24] is an unsupervised approach that constructs a phrase bank by combining keyphrases from all documents into a corpus. Then, AutoKeyGen considers lexical- and semantic-level similarities for selecting top candidate keyphrases (present and absent) for each input document.

Evaluation Metrics. We evaluated our approach using different metrics: Precision, Recall, and $F_1$ scores. The Precision is computed as the number of correctly-matched keyphrases over all predicted keyphrases.

Given a list of predicted keyphrases $\mathcal{Y} = (y_1, \ldots, y_{|\mathcal{Y}|})$, we select the top-$k$ ranked keyphrases $\mathcal{Y}_k = (y_1, \ldots, y_{\min(k,|\mathcal{Y}|)})$ and compare with the top-$k$ ranked keyphrases in the ground-truth set. We set $k = \{5, 10\}$ for present keyphrases and $k = \{10, 20\}$ for absent ones in our experiments. Following previous works [24, 30], we use the Porter Stemmer from the NLTK library\(^2\) v3.7 to compute exact-matching between the top-$k$ predicted ($\mathcal{Y}_k$) and the ground-truth ($\mathcal{Y}^{gold}$) keyphrases. The precision of the top-$k$ predicted keyphrases is defined as

$$P@k = \frac{|\mathcal{Y}_k \cap \mathcal{Y}^{gold}|}{|\mathcal{Y}_k|}. \quad (6)$$

\(^2\) [https://www.nltk.org/index.html](https://www.nltk.org/index.html).
The Recall is calculated as how many correctly-matched keyphrases among all ground-truth keyphrases. Formally, the Recall is defined as

$$R@k = \frac{|Y_k \cap Y^{gold}|}{|Y^{gold}|}. \quad (7)$$

and the $F_1@k$-score is defined as the harmonic mean of $P@k$ and $R@k$

$$F_1@k = 2 \times \frac{P@k \times R@k}{P@k + R@k}. \quad (8)$$

Although the exact-matching metric has been used widely in the literature [13], there is still a room for improvement regarding the absent keyphrases evaluation based on semantic similarity. Hence, we propose in Sect. 4.3 a semantic-based matching to evaluate the performance of generated absent keyphrases.

**Hyperparameters.** We performed a grid search to optimize the hyperparameters of our approach. We found the following values yield the best $F_1$-scores. In the PKE component, we tokenized the input text into phrases of 2–4 grams. Further, we considered the top-10 ranked phrases as candidates for present keyphrases. The full setup of our experiments is available at the GitHub repository.\(^3\) For the baseline methods, the hyperparameters were set according to their original papers. In the MAG framework, we adapted the extraction of common entities to cover a larger set of entity types. In addition, we set the other hyperparameters values with the standard configuration\(^4\) of the MAG framework.

4.2 Present Keyphrase Evaluation (Q₁)

To answer Q₁, we evaluated our approach (MULTPAX) vs. different baselines in extracting present keyphrases. As shown in Table 3, MULTPAX significantly outperforms all baselines by a large margin on most datasets with a significant t-test \( p < 0.041 \). This is due to, MULTPAX employs semantic similarity between candidate keyphrases and an input document using the state-of-the-art pre-trained language model in semantic textual matching [29]. In contrast, CopyRNN [15] and AutoKeyGen [24] used sequence-to-sequence models to encode an input document as a low-dimensional vector and decode it back into a sequence of predicted keyphrases.

On the other hand, we find that YAKE does not perform well in detecting present keyphrases from short texts (e.g., papers’ abstracts). Since YAKE relies on statistical features such as words co-occurrence and frequencies, which are efficiently computed only in long texts (e.g., full papers or news). Remarkably, the embedding-based baseline (EmbedRank) achieves comparable results; however, it fails to generate absent keyphrases. In our approach, we extract present keyphrases from text using contextualized embeddings and semantic matching. These findings answer Q₁; by employing pre-trained language models, we can not only efficiently identify present keyphrases from text without labelled data, but we also outperform the state-of-the-art approach (AutoKeyGen).

4.3 Absent Keyphrase Evaluation (Q₂)

We conduct further experiments to evaluate the performance of our approach against two baselines (namely, CopyRNN and AutoKeyGen) in generating absent keyphrases. Following previous work [24], we use the Recall metric (R@10, R@20) based on exact-matching for the performance evaluation as shown in Table 4. Since we used the same experimental setup of CopyRNN and AutoKeyGen approaches, we obtained the evaluation results from their papers [15,24].

Regarding Q₂, we can clearly see that all approaches achieve poor performances when considering exact-matching between predicted and ground-truth
keyphrases. For example, if two keyphrases are semantically similar, e.g., “disaster relief organization” and “crisis responses institute”, these keyphrases will not be considered as a match using the existing metrics. Hence, we found that such metrics are unsuitable for evaluating absent keyphrases. We propose an improved evaluation metric based on the semantic-matching. Formally, let $Y^a$ be predicted keyphrases; $Y^{gold}$ is ground-truth keyphrases. We first embed each keyphrase in $Y^a$ and $Y^{gold}$. Then, we use Cosine distance to compute similarities between the embedding of each keyphrase in $Y$ and $Y^{gold}$. We set a threshold ($> 0.5$) for similarities scores to consider semantic-matching between $Y$ and $Y^{gold}$. The two last rows in Table 4 show the evaluation results of $R@10$ and $R@20$ based on semantic-matching compared to exact-matching in absent keyphrase extraction.

The AutoKeyGen baseline demonstrates competitive performance in generating absent keyphrases on the NUS dataset. However, the generated keyphrases by AutoKeyGen are limited to the ones from the phrase bank of each dataset. In contrast, our approach leverages public knowledge graphs (such as DBpedia and BabelNet) to obtain relevant phrases as candidates for absent keyphrases.

Limitation of Our Work. In our experiment, we used the MAG framework to connect present keyphrases to DBpedia knowledge graph (see Sect. 3.3). In the SemEval2010 and Krapivin datasets, we were unable to link present keyphrases, due to the lack of coverage for these keyphrases in the DBpedia knowledge graph. That is the reason for the missing values shown in the last two rows of Table 4 for these datasets. In our future work, we plan to integrate other knowledge graphs (e.g., YAGO and Wikidata) to extend the coverage of entity linking in the MAG framework.

4.4 Ablation Study ($Q_3$)

To answer $Q_3$, we analysed the impact of each component of our framework on the overall performance. For this purpose, we set up four variants of our framework. The first variant MULTPAX-PKE was dedicated for only extracting present keyphrases, i.e., no absent keyphrase generation and thus no linking with knowledge graphs. We also created two variants of MULTPAX with the purpose of evaluating the generation of absent keyphrases, namely MULTPAX-AKE$_{DBpedia}$ and MULTPAX-AKE$_{BabelNet}$. Furthermore, we configured the MAG framework to link present keyphrases only with DBpedia in case of MULTPAX-AKE$_{DBpedia}$, and only with BabelNet for MULTPAX-AKE$_{BabelNet}$. Finally, we benchmarked the entire framework MULTPAX$_{Full}$ as our fourth variant.

Table 5 reports the evaluation results of each component in terms of semantic-matching $F_1@5$, and $F_1@10$ on the Inspec dataset, since it contains the highest ratio of absent keyphrases among the benchmark datasets. We can see that the performance of MULTPAX-PKE is improved when linking with knowledge graphs, e.g., MULTPAX-AKE$_{DBpedia}$ outperforms MULTPAX-PKE by $+0.41$ in $F_1@10$. In addition, we noticed that our approach could retrieve more terms from DBpedia than BabelNet, since DBpedia contains more semantic ontologies (approximately 3.5 millions instances) extracted from Wikipedia information boxes. Finally, our MULTPAX$_{Full}$ showed an improved performance with
F₁-scores (0.911 in F₁@5, 0.763 in F₁@10) when incorporating both knowledge graphs (i.e., DBPedia and BabelNet) compared with individual variants. These findings conclude that each component of MULTPAX contributes to the overall performance of our framework and answers our last research question Q₃.

5 Conclusion

This paper presents MULTPAX framework, a multitask approach for extracting present and absent keyphrases, including three components: i) Present Keyphrase Extraction, ii) Absent Keyphrases Generation, and iii) Keyphrases Semantic Matching. In our approach, we employ a pre-trained language model (BERT) and knowledge graphs (DBPedia and BabelNet) in keyphrase extraction. Our experiments showed that pre-trained language models are capable of efficiently extracting present keyphrases. Furthermore, knowledge graphs proved to be valuable resources for generating keyphrases that are absent, especially in short text. In our future work, we plan to apply a bootstrapped approach for keyphrase extraction from DBPedia abstracts to find more relevant terms. In particular, we intend to apply MULTPAX recursively on the abstracts of DBPedia entities. In addition, we will experiment with other knowledge graphs (e.g., YAGO and Wikidata) to extend the coverage of entity link in the MAG framework.

Supplemental Material Statement. We implemented our framework in Python 3.7, the source code and how-to-run instructions can be found at the GitHub repository.
